## Coding and cryptography

#### Cryptography needs different difficult problems

- factorization
- discrete log
- SVP for lattices
- syndrome decoding problem

For code-based cryptography, the security of cryptosystems is usually related to the problem of syndrome decoding.

- 4 周 ト 4 戸 ト 4 戸 ト

## Syndrome decoding problem

#### Syndrome decoding

For a given syndrome s, find x of small Hamming weight such that  $Hx^t = y$  with H a random matrix.

Problem studied for many years with a well known complexity. Caracteristics :

- NP-hard
- usually fast
- A priori resisting to quantum computer

Best known attacks : Information Set Decoding and variations : FS '09, MMT '11, BJMT '12

Complexity of attacks seem converging to a certain stabilization.

- 4 同 6 4 日 6 4 日 6

## Codes and cryptography

Finding alternative to RSA and NT based system : major issue

- McEliece cryptosystem : usually lead to very large public keys (a few hundred thousand) too large for general utilization
- lattices : very close to codes but with a different metric : NTRU '95 : double circulant structure : first non number theory based system with small keys, the LWE, Ring-LWE, ...
- **codes** : different systems proposed in the '00's : structure + structure  $\rightarrow$  too much structure for attack (30.000b)
- recently 2012 : MDPC codes for crypto, NTRU like system , with random small weight double-circulant codes 4800b.
- rank metric ??

・ロト ・同ト ・ヨト ・ヨト

## Rank metric codes

The rank metric is defined in finite extensions.

- $\mathbb{F}_q$  a finite field with q a power of a prime.
- $\mathbb{F}_{q^m}$  an extension of degree m of  $\mathbb{F}_q$ .
- $B = (b_1, ..., b_m)$  a basis of  $F_{q^m}$  over  $F_q$ .

 $\mathbb{F}_{q^m}$  can be seen as a vector space on  $\mathbb{F}_q$ .

- C a linear code over  $\mathbb{F}_{q^m}$  of dimension k and length n.
- G a  $k \times n$  generator matrix of the code C.
- *H* a  $n \times (n k)$  parity check matrix of *C*, GH = 0.

イロト イポト イヨト イヨト

## Rank metric

Words of the code C are *n*-uplets with coordinates in  $\mathbb{F}_{q^m}$ .

$$v = (v_1, \ldots, v_n)$$

with 
$$v_i \in \mathbb{F}_{q^m}$$
.  
Any coordinate  $v_i = \sum_{j=1}^m v_{ij} b_j$  with  $v_{ij} \in \mathbb{F}_q$ .

#### Métrique rang

v has rank r iff the rank of  $V = (v_{ij})_{ij}$  is r.

Philippe Gaborit, Gaetan Murat, Olivier Ruatta, Gilles Zémor Low Rank Parity Check codes and their application to cryptograf

< 日 > < 同 > < 三 > < 三 >

## Rank syndrome decoding problem (RSD)

#### Syndrome decoding

Let H be a  $((n - k) \times n)$  matrix over  $F_{q^m}$  with  $k \le n$ ,  $s \in F_{q^m}^k$  and r an integer. The problem is to find x such that rank(x) = r and  $Hx^t = s$ 

- induces short public keys
- not proven NP-hard (does not mean it is not !)

- 4 回 ト 4 ヨト 4 ヨト

## Support analogy

The support of a word in Hamming metric  $x(x_1, x_2, \dots, x_n)$  is the set of positions  $x_i \neq 0$ 

- how to recover a small Hamming word associated to a given syndrome?

- 1) find the support of the word (guess ! !)
- 2) solve a system to recover the coordinates values

< 日 > < 同 > < 三 > < 三 >

#### • Support of a word in rank metric

The support of a word  $x(x_1, x_2, \dots, x_n)$  of rank r is a space E of dim r such that  $\forall x_i, x_i \in E$ .

- how to recover a word associated to a given syndrome?
- 1) find the support (guess it !)
- 2) solve a system from the syndrome equations to recover the  $x_i \in E$
- **remark :** for Hamming Newton binomial, for rank distance Gaussian binomial  $! \rightarrow$  complexity grows faster.
- $\Rightarrow$  rank metric induces smaller parameters for a given complexity

(日)

## Best known attacks

#### A.Ourivski et T.Johannson '02 :

- basis enumeration :  $\leq (k + r)^3 q^{(r-1)(m-r)+2}$  (improvement on the polynomial part of Chabaud-Stern '96)
- coordinate enumeration :  $\leq (k+r)^3 r^3 q^{(r-1)(k+1)}$

#### More recently (2012) Gaborit, Schrek, Ruatta :

-  $(m(n-k))^3 q^{\frac{(k+1)(r-1)m}{n}}$ , generalization of ISD for rank metrix -  $O(r^3 k^3 q^{r \lceil \frac{(r+1)(k+1)-(n+1)}{r} \rceil})$  with algebraic attacks

## Rank metric and cryptography

## Classical setting for code based crypto : the MacELiece scheme

• Gabidulin codes are the analogous of Reed-Solomon codes

 $\rightarrow$  possible to design a system based on Gabidulin codes : GPT cryptosystem '91

 $\operatorname{problem}$  : as Reed-Solomon codes : the Gabidulin codes are difficult to hide

 $\rightarrow$  attacks (OJ '02,..) and new constructions (FL '05) and new attacks (Overbeke '06,..) probably possible to eventually find a resistant construction but doubt on structural attacks

・ロト ・同ト ・ヨト ・ヨト

## Decoding in rank metric

- Gabidulin [n, k] codes over  $F_{q^n}$  decode up to r = (n k)/2
- simple construction possible to decode random errors up to GVR, but slow decoding and difficult to hide

#### Are there alternatives?

What does exist in Hamming distance?

- Reed-Solomon codes and derivatives (BCH, Goppa, ...)
- LDPC codes : dual matrix with low weight

- 4 同 6 4 日 6 4 日 6

## LRPC codes

LDPC : dual with low weight (ie : small support)

 $\rightarrow$  equivalent for rank metric : dual with small rank support

#### Definition

A Low Rank Parity Check (LRPC) code of rank d, length n and dimension k over  $F_{q^m}$  is a code such that the code has for parity check matrix, a  $(n - k) \times n$  matrix  $H(h_{ij})$  such that the sub-vector space of  $F_{q^m}$  generated by its coefficients  $h_{ij}$  has dimension at most d. We call this dimension the weight of H.

In other terms : all coefficients  $h_{ij}$  of H belong to the same 'low' vector space  $F < F_1, F_2, \dots, F_d >$  of  $F_{q^m}$  of dimension d.

・ロト ・得ト ・ヨト ・ヨト

## Decoding LRPC codes

Idea : as usual recover the support and then deduce the coordinates values.

Let  $e(e_1, ..., e_n)$  be an error vector of weight r, ie :  $\forall e_i : e_i \in E$ , and dim(E)=r. Suppose  $H.e^t = s = (s_1, ..., s_{n-k})^t$ .

 $e_i \in E < E_1, ..., E_r >, h_{ij} \in F < F_1, F_2, \cdots, F_d >$  $\Rightarrow s_k \in < E_1F_1, ..., E_rF_d >$ 

 $\Rightarrow$  if n - k is large enough, it is possible to recover the product space  $\langle E_1 F_1, ..., E_r F_d \rangle$ 

イロト イポト イヨト イヨト 三日

## Decoding LRPC codes

Syndrome  $s(s_1, ..., s_{n-k})$ :  $S = \langle s_1, ..., s_{n-k} \rangle \subset \langle E_1F_1, ..., E_rF_d \rangle$ Suppose  $S = \langle E.F \rangle \Rightarrow$  possible to recover E. Let  $S_i = F_i^{-1}.S$ , since  $S = \langle E.F \rangle = \langle F_iE_1, F_iE_2, ..., F_iE_r, ... \rangle \rightarrow E \subset S_i$ 

#### $\textbf{E}=\textbf{S}_1\cap\textbf{S}_2\cap\dots\cap\textbf{S}_d$

Philippe Gaborit, Gaetan Murat, Olivier Ruatta, Gilles Zémor Low Rank Parity Check codes and their application to cryptograf

- 4 回 ト 4 ヨ ト 4 ヨ ト

## General decoding of LRPC codes

Let y = xG + e

- Syndrome space computation Compute the syndrome vector H.y<sup>t</sup> = s(s<sub>1</sub>, · · · , s<sub>n-k</sub>) and the syndrome space S =< s<sub>1</sub>, · · · , s<sub>n-k</sub> >.
- **2** Recovering the support *E* of the error  $S_i = F_i^{-1}S$ ,  $E = S_1 \cap S_2 \cap \cdots \cap S_d$ ,
- **Orrection Set up and Set up and**

・ロト ・ 同ト ・ ヨト ・ ヨト

-

Recovering the message x Recover x from the system xG = y - e.

## Decoding of LRPC

#### • Conditions of success

- $S = \langle F.E \rangle \Rightarrow \mathsf{rd} \le \mathsf{n-k}.$
- possibility that  $dim(S) \neq n-k \Rightarrow$  probabilistic decoding with error failure in  $q^{-(n-k-rd)}$
- if d = 2 can decode up to (n k)/2 errors.
- Complexity of decoding : very fast symbolic matrix inversion  $O(m(n-k)^2)$
- Comparison with Gabidulin codes : probabilistic, decoding failure, but as fast.

## Application to cryptography

 $\bullet$  a new family of decodable codes with a low structure, no use of isometry

McEliece setting :
Public key : G LRPC code : [n, k] of weight d which can decode up to errors of weight r
Public key : G' = MG
Secret key : M

#### • Encryption

c=mG' + e , e of rank r

#### • Decryption

Decode  $H.c^t$  in e, then recover m.

• Smaller size of key : double circulant LRPC codes : H=(I A), A circulant matrix

Philippe Gaborit, Gaetan Murat, Olivier Ruatta, Gilles Zémor

Low Rank Parity Check codes and their application to cryptograp

## Application to cryptography

#### • Attacks on the system

- message attack : decode a word of weight r for a [n, k] random code

- structural attack : recover the LRPC structure  $\rightarrow$  a [n, n-k] LRPC matrix of weight *d* contains a word with  $\frac{n}{d}$ first zero positions. Searching for a word of weight *d* in a  $[n - \frac{n}{d}, n - k - \frac{n}{d}]$  code.

#### • Attack on the double circulant structure

as for lattices or codes (with Hamming distance) no specific more efficient attack exists exponentially better than decoding random codes.

э

## Conclusion

- LRPC : new family of rank codes with an efficient probabilistic decoding algorithm
- Application to cryptography in the spirit of NTRU and MDPC
- Very small size of keys, comparable to RSA
- More studies need to be done but very good potentiality

・ロト ・同ト ・ヨト ・ヨト
