# Spectral Orbits and Peak-to-Average Power Ratio of Boolean Functions with respect to the $\{I, H, N\}^{n}$ Transform 

Lars Eirik Danielsen and Matthew G. Parker<br>The Selmer Center, Department of Informatics, University of Bergen, PB 7800, N-5020 Bergen, Norway<br>\{larsed, matthew\}@ii.uib.no<br>http://www.ii.uib.no/~\{larsed, matthew\}

#### Abstract

We enumerate the inequivalent self-dual additive codes over $\mathrm{GF}(4)$ of blocklength $n$, thereby extending the sequence A090899 in The On-Line Encyclopedia of Integer Sequences from $n=9$ to $n=12$. These codes have a well-known interpretation as quantum codes. They can also be represented by graphs, where a simple graph operation generates the orbits of equivalent codes. We highlight the regularity and structure of some graphs that correspond to codes with high distance. The codes can also be interpreted as quadratic Boolean functions, where inequivalence takes on a spectral meaning. In this context we define $\mathrm{PAR}_{I H N}$, peak-to-average power ratio with respect to the $\{I, H, N\}^{n}$ transform set. We prove that $\mathrm{PAR}_{I H N}$ of a Boolean function is equivalent to the the size of the maximum independent set over the associated orbit of graphs. Finally we propose a construction technique to generate Boolean functions with low $\mathrm{PAR}_{I H N}$ and algebraic degree higher than 2 .

## 1 Self-Dual Additive Codes over GF(4)

A quantum error-correcting code with parameters [ $[n, k, d]]$ encodes $k$ qubits in a highly entangled state of $n$ qubits such that any error affecting less than $d$ qubits can be detected, and any error affecting at most $\frac{d-1}{2}$ qubits can be corrected. A quantum code of the stabilizer type corresponds to a code $\mathcal{C} \subset \operatorname{GF}(4)^{n}$ [1]. We denote $\mathrm{GF}(4)=\left\{0,1, \omega, \omega^{2}\right\}$, where $\omega^{2}=\omega+1$. Conjugation in $\mathrm{GF}(4)$ is defined by $\bar{x}=x^{2}$. The trace map, $\operatorname{tr}: \mathrm{GF}(4) \mapsto \mathrm{GF}(2)$, is defined by $\operatorname{tr}(x)=x+\bar{x}$. The trace inner product of two vectors of length $n$ over GF(4), $\boldsymbol{u}$ and $\boldsymbol{v}$, is given by $\boldsymbol{u} * \boldsymbol{v}=\sum_{i=1}^{n} \operatorname{tr}\left(u_{i} \overline{v_{i}}\right)$. Because of the structure of stabilizer codes, the corresponding code over $\operatorname{GF}(4), \mathcal{C}$, will be additive and satisfy $\boldsymbol{u} * \boldsymbol{v}=0$ for any two codewords $\boldsymbol{u}, \boldsymbol{v} \in \mathcal{C}$. This is equivalent to saying that the code must be self-orthogonal with respect to the trace inner product, i.e., $\mathcal{C} \subseteq \mathcal{C}^{\perp}$, where $\mathcal{C}^{\perp}=\left\{\boldsymbol{u} \in \operatorname{GF}(4)^{n} \mid \boldsymbol{u} * \boldsymbol{c}=0, \forall \boldsymbol{c} \in \mathcal{C}\right\}$.

We will only consider codes of the special case where the dimension $k=0$. Zero-dimensional quantum codes can be understood as highly-entangled single quantum states which are robust to error. These codes map to additive codes
over GF(4) which are self-dual [2], $\mathcal{C}=\mathcal{C}^{\perp}$. The number of inequivalent selfdual additive codes over GF(4) of blocklength $n$ has been classified by Calderbank et al. [1 for $n \leq 5$, by Höhn [3 for $n \leq 7$, by Hein et al. 4] for $n \leq 7$, and by Glynn et al. [5] for $n \leq 9$. Moreover, Glynn has recently posted these results as sequence A090899 in The On-Line Encyclopedia of Integer Sequences [6]. We extend this sequence from $n=9$ to $n=12$ both for indecomposable and decomposable codes as shown in table 1 . Table 2 shows the number of inequivalent indecomposable codes by distance. The distance, $d$, of a self-dual additive code over $\operatorname{GF}(4), \mathcal{C}$, is the smallest weight (i.e., number of nonzero components) of any nonzero codeword in $\mathcal{C}$. A database of orbit representatives with information about orbit size, distance, and weight distribution is also available [7].

Table 1: Number of Inequivalent Indecomposable ( $i_{n}$ ) and (Possibly) Decomposable $\left(t_{n}\right)$ Self-Dual Additive Codes Over GF(4)

| $n$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $i_{n}$ | 1 | 1 | 1 | 2 | 4 | 11 | 26 | 101 | 440 | 3,132 | 40,457 | $1,274,068$ |
| $t_{n}$ | 1 | 2 | 3 | 6 | 11 | 26 | 59 | 182 | 675 | 3,990 | 45,144 | $1,323,363$ |

Table 2: Number of Indecomposable Self-Dual Additive Codes Over GF(4) by Distance

| $d \backslash n$ | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| :---: | :---: | :---: | :---: | :---: | :---: | ---: | ---: | ---: | ---: | ---: | :---: |
| 2 | 1 | 1 | 2 | 3 | 9 | 22 | 85 | 363 | 2,436 | 26,750 | 611,036 |

## 2 Graphs, Boolean Functions, and LC-Equivalence

A self-dual additive code over GF(4) corresponds to a graph state [4] if its generator matrix, $G$, can be written as $G=\Gamma+\omega I$, where $\Gamma$ is a symmetric matrix over GF(2) with zeros on the diagonal. The matrix $\Gamma$ can be interpreted as the adjacency matrix of a simple undirected graph on $n$ vertices. It has been shown by Schlingemann and Werner [8], Grassl et al. [9], Glynn [10], and Van den Nest et al. 11 that all stabilizer states can be transformed into an equivalent graph state. Thus all self-dual additive codes over GF(4) can be represented by graphs. These codes also have another interpretation as quadratic Boolean functions over $n$ variables. A quadratic function, $f$, can be represented
by an adjacency matrix, $\Gamma$, where $\Gamma_{i, j}=\Gamma_{j, i}=1$ if $x_{i} x_{j}$ occurs in $f$, and $\Gamma_{i, j}=0$ otherwise.

Example 1. A self-dual additive code over GF(4) with parameters $[[6,0,4]]$ is generated by the generator matrix

$$
\left(\begin{array}{cccccc}
\omega & 0 & 0 & 1 & 1 & 1 \\
0 & \omega & 0 & \omega^{2} & 1 & \omega \\
0 & 0 & \omega & \omega^{2} & \omega & 1 \\
0 & 1 & 0 & \omega & \omega^{2} & 1 \\
0 & 0 & 1 & \omega & 1 & \omega^{2} \\
1 & \omega^{2} & 0 & \omega & 0 & 0
\end{array}\right) .
$$

We can transform the generator matrix into the following generator matrix of an equivalent code corresponding to a graph state,

$$
\left(\begin{array}{cccccc}
\omega & 0 & 0 & 1 & 1 & 1 \\
0 & \omega & 1 & 1 & 0 & 1 \\
0 & 1 & \omega & 1 & 1 & 0 \\
1 & 1 & 1 & \omega & 1 & 1 \\
1 & 0 & 1 & 1 & \omega & 0 \\
1 & 1 & 0 & 1 & 0 & \omega
\end{array}\right)=\Gamma+\omega I
$$

$\Gamma$ is the adjacency matrix of the graph shown in fig. $1(\mathrm{a})$ It can also be represented by the quadratic Boolean function $f(\boldsymbol{x})=x_{0} x_{3}+x_{0} x_{4}+x_{0} x_{5}+x_{1} x_{2}+$ $x_{1} x_{3}+x_{1} x_{5}+x_{2} x_{3}+x_{2} x_{4}+x_{3} x_{4}+x_{3} x_{5}$.

Fig. 1: The LC Orbit of the $[[6,0,4]]$ "Hexacode"

Recently, Glynn et al. [510 has re-formulated the primitive operations that map equivalent self-dual additive codes over GF(4) to each other as a single, primitive operation on the associated graphs. This symmetry operation is referred to as Vertex Neighbourhood Complementation (VNC). It was also discovered independently by Hein et al. [4] and by Van den Nest et al. 11. The
identification of this problem as a question of establishing the local unitary equivalence between those quantum states that can be represented as graphs or Boolean functions was presented by Parker and Rijmen at SETA'01 [12]. Graphical representations have also been identified in the context of quantum codes by Schlingemann and Werner [8] and by Grassl et al. 9]. VNC is another name for Local Complementation (LC), referred to in the context of isotropic systems by Bouchet 1314 . LC is defined as follows.

Definition 1. Given a graph $G=(V, E)$ and a vertex $v \in V$. Let $N_{v} \subset V$ be the neighbourhood of $v$, i.e., the set of vertices adjacent to $v$. The subgraph induced by $N_{v}$ is complemented to obtain the LC image $G^{v}$.
It is easy to verify that $\left(G^{v}\right)^{v}=G$.
Theorem 1 (Glynn et al. [5]). Two graphs $G$ and $H$ correspond to equivalent self-dual additive codes over $\mathrm{GF}(4)$ iff there is a finite sequence of vertices $v_{1}, v_{2}, \ldots, v_{s}$, such that $\left(\left(\left(G^{v_{1}}\right)^{v_{2}}\right) \cdots\right)^{v_{s}}=H$.

The symmetry rule can also be described in terms of quadratic Boolean functions.

Definition 2. If the quadratic monomial $x_{i} x_{j}$ occurs in the algebraic normal form of the quadratic Boolean function $f$, then $x_{i}$ and $x_{j}$ are mutual neighbours in the graph represented by $f$, as described by the $n \times n$ symmetric adjacency matrix, $\Gamma$, where $\Gamma_{i, j}=\Gamma_{j, i}=1$ if $x_{i} x_{j}$ occurs in $f$, and $\Gamma_{i, j}=0$ otherwise. The quadratic Boolean functions $f$ and $f^{\prime}$ are LC equivalent if

$$
f^{\prime}(\boldsymbol{x})=f(\boldsymbol{x})+\sum_{\substack{j, k \in N_{a} \\ j<k}} x_{j} x_{k} \quad(\bmod 2)
$$

where $a \in \mathbb{Z}_{n}$ and $N_{a}$ comprises the neighbours of $x_{a}$ in the graph representation of $f$.

A finite number of repeated applications of the LC operation generates the orbit classes presented in this paper and, therefore, induces an equivalence between quadratic Boolean functions. We henceforth refer to this equivalence as $L C$ equivalence and the associated orbits as $L C$ orbits. If the graph representations of two self-dual additive codes over GF(4) are isomorphic, they are also considered to be equivalent. This corresponds to a permutation of the labels of the vertices in the graph or the variables in the Boolean function. We only count members of an LC orbit up to isomorphism. As an example, fig. 1 shows the graph representation of the two only non-isomorphic members in the orbit of the $[[6,0,4]]$ "Hexacode".

A recursive algorithm, incorporating the package nauty [15] to check for graph isomorphism, was used to generate the LC orbits enumerated in table 1. Only the LC orbits of indecomposable codes (corresponding to connected graphs) were generated, since all decomposable codes (corresponding to unconnected graphs) can easily be constructed by combining indecomposable codes of shorter lengths.

Consider, (a) self-dual additive codes over GF (4) of blocklength $n$, (b) pure quantum states of $n$ qubits which are joint eigenvectors of a commuting set of
operators from the Pauli Group [1], (c) quadratic Boolean functions of $n$ variables, (d) undirected graphs on $n$ vertices. Then, under a suitable interpretation, we consider objects (a), (b), (c), and (d) to be mathematically identical.

## 3 Regular Graph Structures

Although a number of constructions for self-dual additive codes over GF(4) exist [5|16], it appears that the underlying symmetry of their associated graphs has not been identified or exploited to any great extent. We highlight the regularity and structure of some graphs that correspond to self-dual additive codes over $\mathrm{GF}(4)$ with high distance. Of particular interest are the highly regular "nested clique" graphs. Fig. 2 shows a few examples of such graphs. There is an upper bound on the possible distance of self-dual additive codes over GF (4) [2]. Codes that meet this bound are called extremal. Other bounds on the distance also exist [17]. Of the codes corresponding to graphs shown in fig. 2, the $[[6,0,4]]$, $[[12,0,6]]$, and $[[20,0,8]]$ codes are extremal. To find the "nested clique" graph representations, one may search through the appropriate LC orbits. Also note that all "nested clique" graphs we have identified so far have circulant adjacency matrices. An exhaustive search of all graphs with circulant adjacency matrices of up to 30 vertices has been performed.

If $d$ is the distance of a self-dual additive code over GF(4), then every vertex in the corresponding graph must have a vertex degree of at least $d-1$. This follows from the fact that a vertex with degree $\delta$ corresponds to a row in the generator matrix, and therefore a codeword, of weight $\delta+1$. All the graphs shown in fig. 2 satisfy the minimum possible regular vertex degree for the given distance. Some extremal self-dual additive codes over GF(4) do not have any regular graph representation, for example the unique $[[11,0,5]]$ and $[[18,0,8]]$ codes. For codes of length above 25 and distance higher than 8 the graph structures get more complicated. For example, with a non-exhaustive search, we did not find a graph representation of a [[30, 0, 12]] code with regular vertex degree lower than 15.

## 4 The $\{I, H, N\}^{n}$ Transform

LC-equivalence between two graphs can be interpreted as an equivalence between the generalised Fourier spectra of the two associated Boolean functions.

Definition 3. Let

$$
I=\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right), \quad H=\frac{1}{\sqrt{2}}\left(\begin{array}{cc}
1 & 1 \\
1 & -1
\end{array}\right), \quad N=\frac{1}{\sqrt{2}}\left(\begin{array}{cc}
1 & i \\
1 & -i
\end{array}\right),
$$

where $i^{2}=-1$, be the Identity, Hadamard, and Negahadamard kernels, respectively.

These are unitary matrices, i.e., $I I^{\dagger}=H H^{\dagger}=N N^{\dagger}=I$, where $\dagger$ means conjugate transpose. Let $f$ be a Boolean function on $n$ variables and $s=2^{-\frac{n}{2}}(-1)^{f(\boldsymbol{x})}$

(a) The $[[6,0,4]]$
" 2 -clique of 3 -cliques"

(b) The $[[12,0,6]]$
" 3 -clique of 4 -cliques"

(c) The $[[18,0,6]]$
" 2 -clique of 3 -cliques of 3 -cliques"

Fig. 2: "Nested Clique" Graphs
be a vector of length $2^{n}$. Let $s_{j}$, where $j \in \mathbb{Z}_{2^{n}}$, be the $j$ th coordinate of $s$. Let $U=U_{0} \otimes U_{1} \otimes \cdots \otimes U_{n-1}$ where $U_{k} \in\{I, H, N\}$, and $\otimes$ is the tensor product (or Kronecker product) defined as

$$
A \otimes B=\left(\begin{array}{ccc}
a_{00} B & a_{01} B & \cdots \\
a_{10} B & a_{11} B & \cdots \\
\vdots & \vdots & \ddots
\end{array}\right)
$$

Let $\boldsymbol{S}=U \boldsymbol{s}$ for any of the $3^{n}$ valid choices of the $2^{n} \times 2^{n}$ transform $U$. Then the set of $3^{n}$ vectors, $\boldsymbol{S}$, is a multispectra with respect to the transform set, $U$, with $3^{n} 2^{n}$ spectral points. We refer to this multispectra as the spectrum with respect to the $\{I, H, N\}^{n}$ transform. (Using a similar terminology, the spectrum with respect to the $\{H\}^{n}$ transform would simply be the well-known WalshHadamard spectrum). It can be shown that the $\{I, H, N\}^{n}$ spectrum of an LC orbit is invariant to within coefficient permutation. Moreover if, for a specific choice of $U, \boldsymbol{S}$ is flat (i.e., $\left.\left|S_{i}\right|=\left|S_{j}\right|, \forall i, j\right)$, then we can write $\boldsymbol{S}=v^{4 f^{\prime}(\boldsymbol{x})+h(\boldsymbol{x})}$, where $f^{\prime}$ is a Boolean function, $h$ is any function from $\mathbb{Z}_{2}^{n}$ to $\mathbb{Z}_{8}$, and $v^{4}=-1$. If the algebraic degree of $h(\boldsymbol{x})$ is $\leq 1$, we can always eliminate $h(\boldsymbol{x})$ by postmultiplication by a tensor product of matrices from $\mathcal{D}$, the set of $2 \times 2$ diagonal and anti-diagonal unitary matrices 18 , an operation that will never change the spectral coefficient magnitudes. Let $M$ be the multiset of $f^{\prime}$ existing within the $\{I, H, N\}^{n}$ spectrum for the subcases where $h(\boldsymbol{x})$ is of algebraic degree $\leq 1$. The $\{I, H, N\}^{n}$-orbit of $f$ is then the set of distinct members of $M$. In particular, if $f$ is quadratic then the $\{I, H, N\}^{n}$-orbit is the LC orbit [18].
Example 2. We look at the function $f(\boldsymbol{x})=x_{0} x_{1}+x_{0} x_{2}$. The corresponding bipolar vector, ignoring the normalization factor, is

$$
\boldsymbol{s}=(-1)^{f(\boldsymbol{x})}=(1,1,1,-1,1,-1,1,1)^{T}
$$

We choose the transform $U=N \otimes I \otimes I$ and get the result

$$
\boldsymbol{S}=U \boldsymbol{s}=\left(v, v^{7}, v^{7}, v, v^{7}, v, v, v^{7}\right)^{T}, \quad v^{4}=-1
$$

We observe that $\left|S_{i}\right|=1, \forall i$, which means that $\boldsymbol{S}$ is flat and can be expressed as

$$
\boldsymbol{S}=v^{4\left(x_{0} x_{1}+x_{0} x_{2}+x_{1} x_{2}\right)+\left(6 x_{0}+6 x_{1}+6 x_{2}+1\right)} .
$$

We observe that $h(\boldsymbol{x})$, the terms that are not divisible by 4 , are all linear or constant. We can therefore eliminate $h(\boldsymbol{x})$, in this case by using the transform

$$
D=\left(\begin{array}{ll}
1 & 0 \\
0 & i
\end{array}\right) \otimes\left(\begin{array}{ll}
1 & 0 \\
0 & i
\end{array}\right) \otimes\left(\begin{array}{cc}
v^{7} & 0 \\
0 & v
\end{array}\right)
$$

We get the result

$$
D \boldsymbol{S}=(-1)^{x_{0} x_{1}+x_{0} x_{2}+x_{1} x_{2}}
$$

and thus $f^{\prime}(\boldsymbol{x})=x_{0} x_{1}+x_{0} x_{2}+x_{1} x_{2}$. The functions $f$ and $f^{\prime}$ are in the same $\{I, H, N\}^{n}$ orbit, and since they are quadratic functions, the same LC orbit. This can be verified by applying the LC operation to the vertex corresponding to the variable $x_{0}$ in the graph representation of either function.

## 5 Peak-to-Average Power Ratio w.r.t. $\{I, H, N\}^{n}$

Definition 4. The peak-to-average power ratio of a vector, $\boldsymbol{s}$, with respect to the $\{I, H, N\}^{n}$ transform [19] is

$$
\operatorname{PAR}_{I H N}(\boldsymbol{s})=2^{n} \max _{\substack{\forall U \in\{I, H, N\}^{n} \\ \forall k \in \mathbb{Z}_{2} n}}\left|S_{k}\right|^{2}, \quad \text { where } \boldsymbol{S}=U \boldsymbol{s} .
$$

If a vector, $s$, has a completely flat $\{I, H, N\}^{n}$ spectrum (which is impossible) then $\operatorname{PAR}_{I H N}(s)=1$. If $s=2^{-\frac{n}{2}}(1,1, \ldots, 1,1)$ then $\operatorname{PAR}_{I H N}(s)=2^{n}$. A typical vector, $s$, will have a $\operatorname{PAR}_{I H N}(s)$ somewhere between these extremes. For quadratic functions, $\mathrm{PAR}_{I H N}$ will always be a power of 2 . The PAR of $s$ can be alternatively expressed in terms of the generalised nonlinearity [19,

$$
\gamma(f)=2^{\frac{n}{2}-1}\left(2^{\frac{n}{2}}-\sqrt{\operatorname{PAR}_{I H N}(s)}\right),
$$

but in this paper we use the PAR measure. Let $s=2^{-\frac{n}{2}}(-1)^{f(\boldsymbol{x})}$, as before. When we talk about the $\mathrm{PAR}_{I H N}$ of $f$ or its associated graph $G$, we mean $\operatorname{PAR}_{I H N}(s)$. It is desirable to find Boolean functions with high generalised nonlinearity and therefore low $\mathrm{PAR}_{I H N}$ [20. $\mathrm{PAR}_{I H N}$ is an invariant of the $\{I, H, N\}^{n}$ orbit and, in particular, the LC orbit. We observe that Boolean functions from LC orbits associated with self-dual additive codes over GF(4) with high distance typically have low $\mathrm{PAR}_{I H N}$. This is not surprising as the distance of a quantum code has been shown to be equal to the recently defined Aperiodic Propagation Criteria distance (APC distance) [20] of the associated quadratic Boolean function, and APC is derived from the aperiodic autocorrelation which is, in turn, the autocorrelation "dual" of the spectra with respect to $\{I, H, N\}^{n}$. Table 3 shows $\mathrm{PAR}_{I H N}$ values for every LC orbit representative for $n \leq 12$.

Table 3: $\mathrm{PAR}_{I H N}$ of LC Orbit Representatives

| $n$ | Number of orbits with specified $\mathrm{PAR}_{I H N}$ |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 2 | 4 | 8 | 16 | 32 | 64 | 128 | 256 | 512 | 1024 | 2048 |
| 1 | 1 |  |  |  |  |  |  |  |  |  |  |
| 2 | 1 |  |  |  |  |  |  |  |  |  |  |
| 3 |  | 1 |  |  |  |  |  |  |  |  |  |
| 4 |  | 1 | 1 |  |  |  |  |  |  |  |  |
| 5 |  | 1 | 2 | 1 |  |  |  |  |  |  |  |
| 6 |  | 1 | 5 | 4 | 1 |  |  |  |  |  |  |
| 7 |  |  | 6 | 14 | 5 | 1 |  |  |  |  |  |
| 8 |  |  | 9 | 52 | 32 | 7 | 1 |  |  |  |  |
| 9 |  |  | 2 | 156 | 212 | 60 | 9 | 1 |  |  |  |
| 10 |  |  | 1 | 624 | 1,753 | 639 | 103 | 11 | 1 |  |  |
| 11 |  |  |  | 3,184 | 25,018 | 10,500 | 1,578 | 163 | 13 | 1 |  |
| 12 |  |  |  | 12,323 | 834,256 | 380,722 | 43,013 | 3,488 | 249 | 16 | 1 |

Definition 5. Let $\alpha(G)$ be the independence number of a graph $G$, i.e., the size of the maximum independent set in $G$. Let $[G]$ be the set of all graphs in the LC orbit of $G$. We then define $\lambda(G)=\max _{H \in[G]} \alpha(H)$, i.e., the size of the maximum independent set over all graphs in the $L C$ orbit of $G$.

Consider as an example the Hexacode which has two non-isomorphic graphs in its orbit (see fig. 11. It is evident that the size of the largest independent set of each graph is 2 , so $\lambda=2$. The values of $\lambda$ for all LC orbits for $n \leq 12$ clearly show that $\lambda$ and $d$, the distance of the associated self-dual additive code over GF(4), are related. LC orbits associated with codes with high distance typically have small values for $\lambda$. Table 4 summarises this observation by giving the ranges of $\lambda$ observed for all LC orbits associated with codes of given lengths and distances. For instance, $[[12,0,2]]$ codes exist with any value of $\lambda$ between 4 and 11 , while $[[12,0,5]]$ and $[[12,0,6]]$ codes only exist with $\lambda=4$.

Table 4: Range of Maximum Independent Set Size

| ${ }^{\text {d }}$ | Range of $\lambda$ for specified $n$ |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| 2 | 1 | 2 | 2,3 | 3,4 | 3-5 | 3-6 | 3-7 | 4-8 | 4-9 | 4-10 | 4-11 |
| 3 |  |  |  | 2 | 3 | 3,4 | 3,4 | 3-5 | 4-6 | 4-7 | 4-8 |
| 4 |  |  |  |  | 2 |  | 3,4 | 3,4 | 3-5 | 4-6 | 4-7 |
| 5 |  |  |  |  |  |  |  |  |  | 4 | 4 |
| 6 |  |  |  |  |  |  |  |  |  |  | 4 |

Definition 6. Let $\Lambda_{n}$ be the minimum value of $\lambda$ over all LC orbits with $n$ vertices.

From table 4 we observe that $\Lambda_{n}=2$ for $n$ from 3 to $6, \Lambda_{n}=3$ for $n$ from 7 to 10 , and $\Lambda_{n}=4$ when $n$ is 11 or 12 .

Theorem 2. $\Lambda_{n+1} \geq \Lambda_{n}$, i.e., $\Lambda_{n}$ is monotonically nondecreasing when the number of vertices is increasing.

Proof. Consider a graph $G=(V, E)$ with $n+1$ vertices. Select a vertex $v$ and let $G^{\prime}$ be the induced subgraph on the $n$ vertices $V \backslash\{v\}$. We generate the LCorbit of $G^{\prime}$. The LC operations may add or remove edges between $G^{\prime}$ and $v$, but the presence of $v$ does not affect the LC orbit of $G^{\prime}$. The size of the largest independent set in the LC orbit of $G^{\prime}$ is at least $\Lambda_{n}$. This is also an independent set in the LC orbit of $G$, so $\Lambda_{n+1} \geq \Lambda_{n}$.

A very loose lower bound on $\Lambda_{n}$ can also be given. Consider a graph containing a clique of size $k$. It is easy to see that an LC operation on any vertex in the clique will produce an independent set of size $k-1$. Thus the maximum clique in an LC orbit, where the largest independent set has size $\lambda$, can not be larger than $\lambda+1$. If $r$ is the Ramsey number $R(k, k+1)$ [21, then it is guaranteed
that all simple undirected graphs with minimum $r$ vertices will have either an independent set of size $k$ or a clique of size $k+1$. It follows that all LC orbits with at least $r$ vertices must have $\lambda \geq k$. Thus $\Lambda_{n} \geq k$ for $n \geq r$. For instance, $R(3,4)=9$, so LC orbits with at least 9 vertices can not have $\lambda$ smaller than 3 .

For $n>12$, we have computed the value of $\lambda$ for some graphs corresponding to self-dual additive codes over GF(4) with high distance. This gives us upper bounds on the value of $\Lambda_{n}$, as shown in table 5. The bounds on $\Lambda_{13}$ and $\Lambda_{14}$ are tight, since $\Lambda_{12}=4$ and $\Lambda_{n+1} \geq \Lambda_{n}$.

Table 5: Upper Bounds on $\Lambda_{n}$

| $n$ | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\Lambda_{n} \leq$ | 4 | 4 | 5 | 5 | 5 | 6 | 6 | 6 | 9 |

For $n=10$, there is a unique LC orbit that satisfies, optimally, $\lambda=3$, $\mathrm{PAR}_{I H N}=8$ and $d=4$. One of the graphs in this orbit is the graph complement of the "double 5 -cycle" graph, shown in fig. 3

Fig. 3: The "Double 5-Cycle" Graph

Theorem 3 (Parker and Rijmen [12]). Given a graph $G=(V, E)$ with a maximum independent set $A \subset V,|A|=\alpha(G)$. Let $\boldsymbol{s}=(-1)^{f(\boldsymbol{x})}$, where $f(\boldsymbol{x})$ is the boolean function representation of $G$. Let $U=\bigotimes_{i \in A} H_{i} \bigotimes_{i \notin A} I_{i}$, i.e., the transform applying $H$ to variables corresponding to vertices $v \in A$ and $I$ to all other variables. Then $\max _{\forall k \in \mathbb{Z}_{2}{ }^{n}}\left|S_{k}\right|^{2}=2^{\alpha(G)}$, where $\boldsymbol{S}=U \boldsymbol{s}$.

Arratia et al. 22 introduced the interlace polynomial $q(G, z)$ of a graph $G$. Aigner and van der Holst [23] later introduced the interlace polynomial $Q(G, z)$. Riera and Parker [24] showed that $q(G, z)$ is related to the $\{I, H\}^{n}$ spectra of the quadratic boolean function corresponding to $G$, and that $Q(G, z)$ is related to the $\{I, H, N\}^{n}$ spectra.

Theorem 4 (Riera and Parker [24]). Let $f$ be a quadratic boolean function and $G$ its associated graph. Then $P A R_{I H N}$ of $f$ is equal to $2^{\operatorname{deg} Q(G, z)}$, where $\operatorname{deg} Q(G, z)$ is the degree of the interlace polynomial $Q(G, z)$.

Theorem 5. If the maximum independent set over all graphs in the LC orbit $[G]$ has size $\lambda(G)$, then all functions corresponding to graphs in the orbit will have $P A R_{I H N}=2^{\lambda(G)}$.

Proof. Let us for brevity define $P(G)=\operatorname{PAR}_{I H N}(s)$, where $s=2^{-\frac{n}{2}}(-1)^{f(\boldsymbol{x})}$, and $f(\boldsymbol{x})$ is the boolean function representation of $G$. From theorem 3 it follows that $P(G) \geq 2^{\lambda(G)}$. Choose $H=(V, E) \in[G]$ with $\alpha(H)=\lambda(G)$. If $|V|=1$ or 2 , the theorem is true. We will prove the theorem for $n \geq 2$ by induction on $|V|$. We will show that $P(H) \leq 2^{\alpha(H)}$, which is equivalent to saying that $P(G) \leq 2^{\lambda(G)}$. It follows from theorem 4 and the definition of $Q(H, z)$ by Aigner and van der Holst [23] that $P(H)=\max \left\{P(H \backslash u), P\left(H^{u} \backslash u\right), P\left(\left(\left(H^{u}\right)^{v}\right)^{u} \backslash u\right)\right\}$. (We recall that $H^{u}$ denotes the LC operation on vertex $u$ of $H$.) Assume, by induction hypothesis, that $P(H \backslash u)=2^{\lambda(H \backslash u)}$. Therefore, $P(H \backslash u)=2^{\alpha(K \backslash u)}$ for some $K \backslash u \in[H \backslash u]$. Note that $K \backslash u \in[H \backslash u]$ implies $K \in[H]$. It must then be true that $\alpha(K \backslash u) \leq \alpha(K) \leq \alpha(H)$, and it follows that $P(H \backslash u) \leq 2^{\alpha(H)}$. Similar arguments hold for $P\left(H^{u} \backslash u\right)$ and $P\left(\left(\left(H^{u}\right)^{v}\right)^{u} \backslash u\right)$, so $P(H) \leq 2^{\alpha(H)}$.

As an example, the Hexacode has $\lambda=2$ and therefore $\mathrm{PAR}_{I H N}=2^{2}=4$.
Corollary 1. Any quadratic Boolean function on $n$ or more variables must have $P A R_{I H N} \geq 2^{\Lambda_{n}}$.

Definition 7. $P A R_{I H}$ is the peak-to-average power ratio with respect to the transform set $\{I, H\}^{n}$, otherwise defined in the same way as $P A R_{I H N}$.

Definition 8. $P A R_{l}$ is the peak-to-average power ratio with respect to the infinite transform set $\{U\}^{n}$, consisting of matrices of the form

$$
U=\left(\begin{array}{cc}
\cos \theta & \sin \theta e^{i \phi} \\
\sin \theta & -\cos \theta e^{i \phi}
\end{array}\right),
$$

where $i^{2}=-1$, and $\theta$ and $\phi$ can take any real values. $\{U\}$ comprises all $2 \times 2$ unitary transforms to within a post-multiplication by a matrix from $\mathcal{D}$, the set of $2 \times 2$ diagonal and anti-diagonal unitary matrices.

Theorem 6 (Parker and Rijmen [12]). If $\boldsymbol{s}$ corresponds to a bipartite graph, then $P A R_{l}(s)=P A R_{I H}(s)$.

It is obvious that $\{I, H\}^{n} \subset\{I, H, N\}^{n} \subset\{U\}^{n}$, and therefore that $\mathrm{PAR}_{I H} \leq$ $\mathrm{PAR}_{I H N} \leq \mathrm{PAR}_{l}$. We then get the following corollary of theorems 5 and 6 .

Corollary 2. If an $L C$ orbit, $[G]$, contains a bipartite graph, then all functions corresponding to graphs in the orbit will have $P A R_{l}=2^{\lambda(G)}$.

Thus, all LC orbits with a bipartite member have $\mathrm{PAR}_{I H N}=\mathrm{PAR}_{l}$. Note that these orbits will always have $\mathrm{PAR}_{l} \geq 2^{\left\lceil\frac{n}{2}\right\rceil}[12$ and that the fraction of LC orbits which have a bipartite member appears to decrease exponentially as the number of vertices increases. In the general case, $\mathrm{PAR}_{I H N}$ is only a lower bound on $\mathrm{PAR}_{l}$. For example, the Hexacode has $\mathrm{PAR}_{I H N}=4$, but a tighter lower bound on $\mathrm{PAR}_{l}$ is 4.486 [12]. (This bound has later been improved to 5.103 [25].)

## 6 Construction for Low PAR $_{I H N}$

So far we have only considered quadratic Boolean functions which correspond to graphs and self-dual additive codes over GF(4). For cryptographic purposes, we are interested in Boolean functions of degree higher than 2. Such functions can be represented by hypergraphs, but they do not correspond to quantum stabilizer codes or self-dual additive codes over GF(4). A non-quadratic Boolean function, $f(\boldsymbol{x})$, can, however, be interpreted as a quantum state described by the probability distribution vector $s=2^{-\frac{n}{2}}(-1)^{f(\boldsymbol{x})}$. A single quantum state corresponds to a quantum code of dimension zero whose distance is the APC distance [20]. The APC distance is the weight of the minimum weight quantum error operator that gives an errored state not orthogonal to the original state and therefore not guaranteed to be detectable.

We are interested in finding Boolean functions of algebraic degree greater than 2 with low $\mathrm{PAR}_{I H N}$, but exhaustive searching becomes infeasible with more than a few variables. We therefore propose a construction technique for nonquadratic Boolean functions with low $\mathrm{PAR}_{I H N}$ using the best quadratic functions as building blocks. Before we describe our construction we must first state what we mean by "low $\mathrm{PAR}_{I H N}$ ". For $n=6$ to $n=10$ we computed $\mathrm{PAR}_{I H N}$ for samples from the space $\mathbb{Z}_{2}^{2^{n}}$, to determine the range of $\mathrm{PAR}_{I H N}$ we can expect just by guessing. Table 6 summarises these results. If we can construct Boolean functions with $\mathrm{PAR}_{I H N}$ lower than the sampled minimum, we can consider our construction to be somewhat successful.

Table 6: Sampled Range of $\mathrm{PAR}_{I H N}$ for $n=6$ to 10

| n | 6 | 7 | 8 | 9 | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| \# samples | 50000 | 20000 | 5000 | 2000 | 1000 |
| ${\text { Range of } \mathrm{PAR}_{\text {IHN }}}^{6.5-25.0}$ | $9.0-28.125$ | $12.25-28.125$ | $14.0625-30.25$ | $18.0-34.03$ |  |

Parker and Tellambura [26|27] proposed a generalisation of the MaioranaMcFarland construction for Boolean functions that satisfies a tight upper bound on PAR with respect to the $\{H, N\}^{n}$ transform (and other transform sets), this being a form of Golay Complementary Set construction and a generalisation of the construction of Rudin and Shapiro and of Davis and Jedwab [28]. Let $p(\boldsymbol{x})$ be a Boolean function on $n=\sum_{j=0}^{L-1} t_{j}$ variables, where $T=\left\{t_{0}, t_{1}, \ldots, t_{L-1}\right\}$ is a set of positive integers and $\boldsymbol{x} \in \mathbb{Z}_{2}^{n}$. Let $\boldsymbol{y}_{\boldsymbol{j}} \in \mathbb{Z}_{2}^{t_{j}}, 0 \leq j<L$, such that $\boldsymbol{x}=\boldsymbol{y}_{\mathbf{0}} \times \boldsymbol{y}_{\mathbf{1}} \times \cdots \times \boldsymbol{y}_{\boldsymbol{L}-\mathbf{1}}$. Construct $p(\boldsymbol{x})$ as follows.

$$
\begin{equation*}
p(\boldsymbol{x})=\sum_{j=0}^{L-2} \theta_{j}\left(\boldsymbol{y}_{\boldsymbol{j}}\right) \gamma_{j}\left(\boldsymbol{y}_{\boldsymbol{j}+\mathbf{1}}\right)+\sum_{j=0}^{L-1} g_{j}\left(\boldsymbol{y}_{\boldsymbol{j}}\right) \tag{1}
\end{equation*}
$$

where $\theta_{j}$ is a permutation: $\mathbb{Z}_{2}^{t_{j}} \rightarrow \mathbb{Z}_{2}^{t_{j+1}}, \gamma_{j}$ is a permutation: $\mathbb{Z}_{2}^{t_{j+1}} \rightarrow \mathbb{Z}_{2}^{t_{j}}$, and $g_{j}$ is any Boolean function on $t_{j}$ variables. It has been shown [27] that the function
$p(\boldsymbol{x})$ will have $\mathrm{PAR}_{H N} \leq 2^{t_{\max }}$, where $t_{\text {max }}$ is the largest integer in $T$. It is helpful to visualise this construction graphically, as in fig. 4. In this example, the size of the largest partition is 3 , so $\mathrm{PAR}_{H N} \leq 8$, regardless of what choices we make for $\theta_{j}, \gamma_{j}$, and $g_{j}$.

Fig. 4: Example of Construction with $\mathrm{PAR}_{H N} \leq 8$

Observe that if we set $L=2, t=t_{0}=t_{1}$, let $\theta_{0}$ be the identity permutation, and $g_{0}=0$, construction (1) reduces to the Maiorana-McFarland construction over $2 t$ variables. Construction (11) can also be viewed as a generalisation of the "path graph", $f(\boldsymbol{x})=x_{0} x_{1}+x_{1} x_{2}+\cdots+x_{n-2} x_{n-1}$, which has optimal PAR with respect to $\{H, N\}^{n}$. Unfortunately, the "path graph" is not a particularly good construction for low $\mathrm{PAR}_{I H N}$. But as we have seen, graphs corresponding to selfdual additive codes over $\mathrm{GF}(4)$ with high distance do give us Boolean functions with low $\mathrm{PAR}_{I H N}$. We therefore propose the following generalised construction.

$$
\begin{equation*}
p(\boldsymbol{x})=\sum_{i=0}^{L-1} \sum_{j=i+1}^{L-1} \Gamma_{i, j}\left(\boldsymbol{y}_{\boldsymbol{i}}\right) \Gamma_{j, i}\left(\boldsymbol{y}_{\boldsymbol{j}}\right)+\sum_{j=0}^{L-1} g_{j}\left(\boldsymbol{y}_{\boldsymbol{j}}\right) \tag{2}
\end{equation*}
$$

where $\Gamma_{i, j}$ is either a permutation: $\mathbb{Z}_{2}^{t_{i}} \rightarrow \mathbb{Z}_{2}^{t_{j}}$, or $\Gamma_{i, j}=0$, and $g_{j}$ is any Boolean function on $t_{j}$ variables. It is evident that $\Gamma$ can be thought of as a "generalised adjacency matrix", where the entries, $\Gamma_{i, j}$, are no longer 0 or 1 but, instead, 0 or permutations from $\mathbb{Z}_{2}^{t_{i}}$ to $\mathbb{Z}_{2}^{t_{j}}$. Construction (1) then becomes a special case where $\Gamma_{i, j}=0$ except for when $j=i+1$ (i.e., the "generalised adjacency matrix" of the "path graph"). In order to minimise $\mathrm{PAR}_{I H N}$ we choose the form of the matrix $\Gamma$ according to the adjacency matrix of a self-dual additive code over GF (4) with high distance. We also choose the "offset" functions, $g_{j}$, to be Boolean functions corresponding to self-dual additive codes over GF(4) with high distance. Finally for the non-zero $\Gamma_{i, j}$ entries, we choose selected permutations, preferably nonlinear to increase the overall degree. Here are some initial results which demonstrate that, using (2), we can construct Boolean functions of algebraic degree greater than 2 with low $\mathrm{PAR}_{I H N}$. (We use an abbreviated ANF notation for some many-term Boolean functions, e.g. 012, 12, 0 is short for $x_{0} x_{1} x_{2}+x_{1} x_{2}+x_{0}$.)

Example 3 ( $n=8$ ). Use the Hexacode graph $f=01,02,03,04,05,12,23,34$, 45,51 as a template. Let $t_{0}=3, t_{1}=t_{2}=t_{3}=t_{4}=t_{5}=1$. (See fig. 5.) We use
the following matrix $\Gamma$.

$$
\Gamma=\left(\begin{array}{cccccc}
0 & 02,1 & 02,1 & 02,1 & 02,1 & 02,1 \\
3 & 0 & 3 & 0 & 0 & 3 \\
4 & 4 & 0 & 4 & 0 & 0 \\
5 & 0 & 5 & 0 & 5 & 0 \\
6 & 0 & 0 & 6 & 0 & 6 \\
7 & 7 & 0 & 0 & 7 & 0
\end{array}\right)
$$

Let $g_{0}\left(\boldsymbol{y}_{\mathbf{0}}\right)=01,02,12$ and all other $g_{j}$ any arbitrary affine functions. Then, using (2) to construct $p(\boldsymbol{x})$ we get $p(\boldsymbol{x})=023,024,025,026,027,01,02,12,13$, $14,15,16,17,34,37,45,56,67$. Then $p(\boldsymbol{x})$ has $\mathrm{PAR}_{I H N}=9.0$.

Fig. 5: Example of Construction with low $\mathrm{PAR}_{I H N}$

Example $4(n=8)$. Use the Hexacode graph $f=01,02,03,04,05,12,23,34$, 45,51 as a template. Let $t_{0}=3, t_{1}=t_{2}=t_{3}=t_{4}=t_{5}=1$. (See fig. 5.) We use the following matrix $\Gamma$.

$$
\Gamma=\left(\begin{array}{cccccc}
0 & 02,1 & 12,0,1,2 & 01,02,12,1,2 & 01,02,12 & 02,12,1,2 \\
3 & 0 & 3 & 0 & 0 & 3 \\
4 & 4 & 0 & 4 & 0 & 0 \\
5 & 0 & 5 & 0 & 5 & 0 \\
6 & 0 & 0 & 6 & 0 & 6 \\
7 & 7 & 0 & 0 & 7 & 0
\end{array}\right)
$$

Let $g_{0}\left(\boldsymbol{y}_{\mathbf{0}}\right)=01,12$ and all other $g_{j}$ any arbitrary affine functions. Then, using (2) to construct $p(\boldsymbol{x})$ we get $p(\boldsymbol{x})=015,016,023,025,026,027,124,125,126$, $127,01,04,12,13,14,15,17,24,25,27,34,37,45,56,67$. Then $p(\boldsymbol{x})$ has $\mathrm{PAR}_{I H N}=9.0$.

Example $5(n=9)$. Use the triangle graph $f=01,02,12$ as a template. Let $t_{0}=t_{1}=t_{2}=3$. (See fig. 6.) Assign the permutations

$$
\begin{aligned}
& \Gamma_{0,1}=\Gamma_{0,2}=(12,0,1,2)(01,2)(02,1,2), \\
& \Gamma_{1,0}=(34,5)(35,4,5)(45,3,4,5) \text {, } \\
& \Gamma_{1,2}=(45,3,4,5)(34,5)(35,4,5) \text {, } \\
& \Gamma_{2,0}=(68,7,8)(78,6,7,8)(67,8) \text {, } \\
& \Gamma_{2,1}=(78,6,7,8)(67,8)(68,7,8) .
\end{aligned}
$$

Let $g_{0}\left(\boldsymbol{y}_{\mathbf{0}}\right)=01,02,12, g_{1}\left(\boldsymbol{y}_{\mathbf{1}}\right)=34,35,45$, and $g_{2}\left(\boldsymbol{y}_{\mathbf{2}}\right)=67,68,78$. Then, using (2) to construct $p(\boldsymbol{x})$ we get, $p(\boldsymbol{x})=0135,0178,0245,0267,1234,1268$, $3467,3568,4578,014,015,016,017,018,023,024,025,028,034,068,125,127$, $128,134,145,167,168,234,235,245,267,268,278,348,357,358,378,456,457$, $458,468,478,567,568,578,05,07,08,13,14,17,23,25,26,28,36,37,38,46$, $56,58,01,02,12,34,35,45,67,68,78$. Then $p(\boldsymbol{x})$ has $\mathrm{PAR}_{I H N}=10.25$.

Fig. 6: Example of Construction with low $\mathrm{PAR}_{I H N}$

The examples of our construction satisfy a low $\mathrm{PAR}_{I H N}$. Further work should ascertain the proper choice of permutations. Finally, there is an even more obvious variation of construction (22, suggested by the graphs of fig. 2 , where the functions $g_{j}$ are chosen either to be quadratic cliques or to be further "nested" versions of construction (2). We will report on this variation in a future paper.
